Typographics Art everything in one file This file contains the README and the main documents of the open-source project Typographics Art (https://typographics-art.org, https://github.com/typographics-art/typoart). It is meant to be handed to an AI assistant as a whole. Good first questions: What is Typographics Art? How is it different from ASCII art? Can a machine still read a work? How do I READ.md ... = ## 2. How Typographics Art Four works: Nikola Tesla, The Great Wave, The Wanderer above the Sea of Fog and Frederick Douglass, each set from a whole text; the original image is the small inset Stationery for the AI age A document a person recognises at a glance, and a machine reads exactly as shown. Try it on typographics-art.org/gallery. • Definition • Readability • Text fidelity • Deutsch: Was ist Typografische Kunst? Eine Definition, Lesbarkeit, Textgenauigkeit und Maschinenlesbarkeit. Typographics Art Definition Typographics Art is the practice of forming images out of text. Every character in the finished work is part of a readable sentence, paragraph, or document. The image emerges from the arrangement of characters, not from pixels, strokes, or separate graphic elements. **about/typographics-art.org/about/typographics-art.pdf)**. Then ask: What is Typographics Art, and can you still read the page?" ## The idea For centuries, letterhead, a sonature and a seal showed at a glance what a paper was and who it was from. **Typographics Art** brings that to the AI age, in three layers: 1. **The document** — Markdown plus a few require sections, hashes and a version chain. On its own, already a sentry. **Im...tot with structure.** 2. **The provenance** — the keys on domains, signatures, a sale seq, a verify tool. This is the piece missing in the world today: signatures exist for software and for photos, but not yet a widespread, readable one for texts addressed to AIs. Keys and signatures **Art** can also be anchored in a public transparency log or plugin the anchor contract are defined (OpenTimestamps on Bitcoin, Sigstore Rekor, or a chain such as Polygon, ~$0.25 for a year). **Art** is open, free, and built to grow, even for the communities. Changing in the process keys, signatures, the seal and the verify tool. And sorry, it does not check anchors. 3. **The picture** — no longer the only, but the reason people unpack reading the space a seal on an envelope needs no explanation. It turns a crypto protocol into an object you recognise, show and bring up. On top of that, traffic formats bundles that collect several works, sealed sends, handoff packages between people and their agents, and signed rules for scaling a centre. **What it is not** ** not a replacement for PDF, and not a security system against a malicious author — a sophisticated forger can still produce a convincing fake. What it does is make tampering detectable and honest work verifiable, cheaply and by anyone. **Who it is for** ** not that they are forensic. It is a possibility, not a guarantee: whether an **Art** actually runs the check depends on every tools sending version models run, and on issuers who use people recognise. Put plainly: stationery for the AI age — letterhead, signature, seal and envelope, things people have used for centuries to show origin and integrity, translated into a form a machine can check and a human still can. **Art** can be used by anyone who has something to say and wants it to arrive as written, rather than "everything in one file", but true, and if it did not exist before. ### How the picture works **ASCII art** builds a picture out of characters, but the characters mean nothing. A person sees a face; a machine sees ` @@@#**+=:. `. The text is gone. **Typographics Art** ** (TG Art) builds a picture out of a *real* text. Every character of the text is set once, in its original order. Only its typography changes: size, weight, and (with is an actions easy. A person sees the picture. A language model, a search engine or a screen reader reads the text, exactly as it was written. A simple work — a picture that is, character for character, its own readable text — is a **Typogram**. A Typogram is delivered as ordinary HTML, SVG or PDF (the text stays real, so any program reads it back), and it can carry structured data or sealed models inside it. **Typogram** project and the methods. ## **Typogram** — What is it? A Typogram is a picture made entirely of text. Every character in the finished work is part of a readable sentence, paragraph, or document. The image emerges from the arrangement of characters, not from pixels, strokes, or separate graphic elements. Like **ASCII art**, a Typogram is built from ordinary characters. Unlike ASCII art, those characters are not arbitrary symbols chosen for their shape — they are the actual words, sentences, and paragraphs of a real text. Nikola Tesla and Wrote" ... monospace, one size) a variable font's size, weight and colour per glyph (with is an optional axis) || Format | plain text | HTML, SVG, PDF with a text layer | **#** What a person sees, and what an AI reads The portrait of Frederick Douglass above is set from its own **Typogram**" (https://typographics-art.org/gallery/douglass.svg), select all and copy, or hand the file to any modern AI. As to my own treatment with text on Octavia Lloyd's pantalon, it was very similar to that of the other sown children, I was not old enough to work in the fels, and there being little else than field work to do, I had a great deal of leisure time. ... ** That is the whole point. **The artwork is also the document.** ** the text is the content; what the picture "shows" at a glance is also a short description of its own, which the generator writes into the SVG's <title> and <desc>. A reader (human or machine) can stop at the picture, or read on into the full text. ## How a machine reads a Typogram **Art** ** (TG Art) is designed so that a machine can recover the exact original text from the picture, and can check that it has not been altered. ### The verification chain 1. **Read the text layer.** The text is stored right in the SVG/PDF. No guesswork is needed. 2. **Check the hash.** The file records a SHA-256 of the canonical text (`<canonical-text id="typogram-text">`). Recompute it and compare. If they match, the text is exactly what the author sealed. 3. **Verify the signature.** The author's public key is published at a well-known address (`/.well-known/typogram-keys.json`). Check the signature against that key. If it matches, the author vouches for the text. 4. **Check the anchor.** The hash was recorded in a public, append-only transparency log at a specific time. This proves the text existed then and has not been changed since. ### Why this matters for AI Today, AI systems read documents with no way to know whether they have been tampered with. A Typogram **Art** ** (TG Art) can be checked automatically, by any model, with no special tools. This is the missing piece for trustworthy AI reading of documents. ## Design principles - **Text is the content.** Every character in the finished work is part of a readable sentence, paragraph, or document. The image emerges from the arrangement of characters, not from pixels, strokes, or separate graphic elements. - **Machine-readable by default.** The text layer is stored right in the file. No guesswork is needed. - **Tamper-evident.** Any change to the text breaks the hash. - **Author-verifiable.** Signatures prove who vouches for the text. - **Publicly anchored.** Transparency logs prove when it existed. - **Open and free.** The format, the tools, and the verification chain are open. Anyone can read, check, and build on them. ## Quick start ### Read a Typogram **Art** ** (TG Art) ** (TG Art) ** (TG Art)
